Chapter 1

Action Principles

The Newtonian synthesis, building on the work of many others, especially of Galileo, should be familiar. You have probably also had some exposure to the Lagrangian, the Euler-Lagrange equations, and to the Hamiltonian principle. Here we wish to show that a mechanical system of point particles, nonrelativistically and relativistically, is derivable from a Lagrange-Hamilton action principle, generalizing earlier principles of least action.

We start by reviewing and generalizing the Lagrange-Hamilton principle for a single particle. The action, $W_{12}$, is defined as the time integral of the Lagrangian, $L$, where the integration extends from an initial configuration or state at time $t_2$ to a final state at time $t_1$:

$$W_{12} = \int_{t_2}^{t_1} dt \, L. \quad (1.1)$$

The integral refers to any path, any line of time development, from the initial to the final state, as shown in Fig. 1.1. The actual time evolution of the system is selected by the principle of stationary action: In response to infinitesimal variations of the integration path, the action $W_{12}$ is stationary—does not have a corresponding infinitesimal change—for variations about the correct path,

![Figure 1.1: A possible path from initial state to final state.](image.png)

1 Version of August 31, 2015
provided the initial and final configurations are held fixed,

\[ \delta W_{12} = 0. \]  

(1.2)

This means that, if we allow infinitesimal changes at the initial and final times, including alterations of those times, the only contribution to \( \delta W_{12} \) then comes from the endpoint variations, or

\[ \delta W_{12} = G_1 - G_2, \]  

(1.3)

where \( G_a, a = 1 \text{ or } 2, \) is a function depending on dynamical variables only at time \( t_a. \) In the following, we will consider three different realizations of the action principle, where, for simplicity, we will restrict our attention to a single particle.

### 1.1 Lagrangian Viewpoint

The nonrelativistic motion of a particle of mass \( m \) moving in a potential \( V(r, t) \) is described by the Lagrangian

\[ L = \frac{1}{2} m \left( \frac{d \mathbf{r}}{dt} \right)^2 - V(r, t). \]  

(1.4)

Here, the independent variables are \( r \) and \( t, \) so that two kinds of variations can be considered. First, a particular motion is altered infinitesimally, that is, the path is changed by an amount \( \delta r: \)

\[ \mathbf{r}(t) \to \mathbf{r}(t) + \delta \mathbf{r}(t). \]  

(1.5)

Second, the final and initial times can be altered infinitesimally, by \( \delta t_1 \) and \( \delta t_2, \) respectively. It is more convenient, however, to think of these time displacements as produced by a continuous variation of the time parameter, \( \delta t(t), \)

\[ t \to t + \delta t(t), \]  

(1.6)

so chosen that, at the endpoints,

\[ \delta t(t_1) = \delta t_1, \quad \delta t(t_2) = \delta t_2. \]  

(1.7)

The corresponding change in the time differential is

\[ dt \to d(t + \delta t) = \left( 1 + \frac{d\delta t}{dt} \right) dt, \]  

(1.8)

which implies the transformation of the time derivative,

\[ \frac{d}{dt} \to \left( 1 - \frac{d\delta t}{dt} \right) \frac{d}{dt}. \]  

(1.9)
Because of this redefinition of the time variable, the limits of integration in the action,
\[
W_{12} = \int_2^1 \left[ \frac{1}{2} m \frac{d^2 r}{dt^2} - dt V \right],
\]
are not changed, the time displacement being produced through \(\delta t(t)\) subject to (1.7). The resulting variation in the action is now
\[
\delta W_{12} = \int_2^1 dt \left\{ m \frac{d}{dt} \left[ \frac{1}{2} m \left( \frac{dr}{dt} \right)^2 + V \right] - \delta t \frac{\partial}{\partial t} V \right\}
+ \delta r \cdot \left[ -m \frac{d^2 r}{dt^2} - \nabla V \right] + \delta t \left( \frac{d}{dt} \left[ \frac{1}{2} m \left( \frac{dr}{dt} \right)^2 + V \right] - \frac{\partial}{\partial t} V \right),
\]
where, in the last form, we have shifted the time derivatives (integrated by parts) in order to isolate \(\delta r\) and \(\delta t\).

Because \(\delta r\) and \(\delta t\) are independent variations, the principle of stationary action implies that the actual motion is governed by
\[
m \frac{d^2 r}{dt^2} = -\nabla V,
\]
\[
\frac{d}{dt} \left[ \frac{1}{2} m \left( \frac{dr}{dt} \right)^2 + V \right] = \frac{\partial}{\partial t} V,
\]
while the total time derivative gives the change at the endpoints,
\[
G = p \cdot \delta r - E \delta t,
\]
with
\[
\text{momentum} = p = m \frac{dr}{dt}, \quad \text{energy} = E = \frac{1}{2} m \left( \frac{dr}{dt} \right)^2 + V.
\]
Therefore, we have derived Newton’s second law [the equation of motion in second-order form], (1.12), and, for a static potential, \(\partial V/\partial t = 0\), the conservation of energy, (1.13). The significance of (1.14) will be discussed later in Section 4.

1.2 Hamiltonian Viewpoint

Using the above definition of the momentum, we can rewrite the Lagrangian as
\[
L = p \cdot \frac{dr}{dt} - H(r, p, t),
\]
where we have introduced the Hamiltonian

\[ H = \frac{p^2}{2m} + V(r, t). \]  

We are here to regard \( r, p, \) and \( t \) as independent variables in

\[ W_{12} = \int_1^2 [p \cdot \delta r - dt H]. \]  

The change in the action, when \( r, p, \) and \( t \) are all varied, is

\[ \delta W_{12} = \int_1^2 dt \left[ p \cdot \frac{d}{dt} \delta r - \delta r \cdot \frac{\partial H}{\partial r} + \delta p \cdot \frac{dr}{dt} - \delta p \cdot \frac{\partial H}{\partial p} - \frac{d\delta t}{dt} H - \delta t \frac{\partial H}{\partial t} \right] \]

\[ = \int_1^2 dt \left[ \frac{d}{dt} (p \cdot \delta r - H \delta t) + \delta r \cdot \left( \frac{\partial}{\partial t} \right) \left( \frac{dH}{dt} - \frac{\partial H}{\partial r} \right) \right. \]

\[ + \delta p \cdot \left( \frac{dr}{dt} - \frac{\partial H}{\partial p} \right) + \delta t \left( \frac{dH}{dt} - \frac{\partial H}{\partial t} \right) \].

The action principle then implies

\[ \frac{dr}{dt} = \frac{\partial H}{\partial p} = \frac{p}{m}, \]  

\[ \frac{dp}{dt} = -\frac{\partial H}{\partial r} = -\nabla V, \]  

\[ \frac{dH}{dt} = \frac{\partial H}{\partial t}, \]  

\[ G = p \cdot \delta r - H \delta t. \]

In contrast with the Lagrangian differential equations of motion, which involve second derivatives, these Hamiltonian equations contain only first derivatives; they are called first-order equations. They describe the same physical system, because when (1.20) is substituted into (1.21), we recover the Lagrangian-Newtonian equation (1.12). Furthermore, if we insert (1.20) into the Hamiltonian (1.17), we identify \( H \) with \( E \). The third equation (1.22) is then identical with (1.13). We also note the equivalence of the two versions of \( G \).

But probably the most direct way of seeing that the same physical system is involved comes by writing the Lagrangian in the Hamiltonian viewpoint as

\[ L = m \frac{1}{2} \left( \frac{dr}{dt} \right)^2 - V - \frac{1}{2m} \left( p - m \frac{dr}{dt} \right)^2. \]

The result of varying \( p \) in the stationary action principle is to produce

\[ p = m \frac{dr}{dt}. \]

But, if we accept this as the definition of \( p \), the corresponding term in \( L \) disappears and we explicitly regain the Lagrangian description. We are justified in
completely omitting the last term on the right side of (1.24), despite its dependence on the variables \( r \) and \( t \), because of its quadratic structure. Its explicit contribution to \( \delta L \) is
\[
- \frac{1}{m} \left( p - m \frac{dr}{dt} \right) \cdot \left( \delta p - m \frac{dr}{dt} \delta r + m \frac{dr}{dt} \frac{d\delta t}{dt} \right),
\] (1.26)
and the equation supplied by the stationary action principle for \( p \) variations, (1.25), also guarantees that there is no contribution here to the results of \( r \) and \( t \) variations.

### 1.3 A Third Viewpoint

Here we take \( r, p, \) and the velocity, \( v, \) as independent variables, so that the Lagrangian is written in the form
\[
L = p \cdot \left( \frac{dr}{dt} - v \right) + \frac{1}{2} mv^2 - V(r,t) \equiv p \cdot \frac{dr}{dt} - H(r,p,v,t),
\] (1.27)
where
\[
H(r,p,v,t) = p \cdot v - \frac{1}{2} mv^2 + V(r,t).
\] (1.28)
The variation of the action is now
\[
\delta W_{12} = \delta \int_2^1 \left[ p \cdot dr - H dt \right]
\]
\[
= \int_2^1 dt \left[ \delta p \cdot \frac{dr}{dt} + p \cdot \frac{d\delta r}{dt} \delta t - \delta r \cdot \frac{\partial H}{\partial r} - \delta p \cdot \frac{\partial H}{\partial p} - \delta v \cdot \frac{\partial H}{\partial v} - \delta \frac{d\delta t}{dt} - H \frac{d\delta t}{dt} \right]
\]
\[
= \int_2^1 dt \left[ \frac{d}{dt} \left( p \cdot \delta r - H \delta t \right) - \delta r \cdot \left( \frac{dH}{dt} + \frac{\partial H}{\partial r} \right) + \delta p \cdot \left( \frac{dr}{dt} - \frac{\partial H}{\partial p} \right) - \delta v \cdot \frac{\partial H}{\partial v} + \delta t \left( \frac{dH}{dt} - \frac{\partial H}{\partial t} \right) \right],
\] (1.29)
so that the action principle implies
\[
\frac{dp}{dt} = - \frac{\partial H}{\partial r} = - \nabla V,
\] (1.30)
\[
\frac{dr}{dt} = \frac{\partial H}{\partial p} = v,
\] (1.31)
\[
0 = - \frac{\partial H}{\partial v} = -p + mv,
\] (1.32)
\[
\frac{dH}{dt} = \frac{\partial H}{\partial t} \]
\[
G = p \cdot \delta r - H \delta t.
\] (1.34)
Notice that there is no equation of motion for \( v \) since \( \frac{dv}{dt} \) does not occur in the Lagrangian, nor is it multiplied by a time derivative. Consequently, (1.32) refers to a single time and is an equation of constraint.

From this third approach, we have the option of returning to either of the other two viewpoints by imposing an appropriate restriction. Thus, if we write (1.28) as
\[
H(r, p, v, t) = \frac{p^2}{2m} + V(r, t) - \frac{1}{2m}(p - mv)^2,
\]
and we adopt
\[
v = \frac{1}{m}p
\]
as the definition of \( v \), we recover the Hamiltonian description, (1.16) and (1.17). Alternatively, we can present the Lagrangian (1.27) as
\[
L = \frac{m}{2} \left( \frac{dr}{dt} \right)^2 - V + (p - mv) \cdot \left( \frac{dr}{dt} - v \right) - \frac{m}{2} \left( \frac{dr}{dt} - v \right)^2.
\]
Then, if we adopt the following as definitions,
\[
v = \frac{dr}{dt}, \quad p = mv,
\]
the resultant form of \( L \) is that of the Lagrangian viewpoint, (1.4). It might seem that only the definition \( v = \frac{dr}{dt} \), inserted in (1.37), suffices to regain the Lagrangian description. But then the next to last term in (1.37) would give the following additional contribution to \( \delta L \), associated with the variation \( \delta r \):
\[
(p - mv) \cdot \frac{d}{dt} \delta r.
\]

The advantage of adopting this third approach, which is characterized by the introduction of additional variables, is particularly conspicuous in the action formulation of electrodynamics, where variables, similar to \( v \), appear for which there are no equations of motion.

### 1.4 Invariance and Conservation Laws

There is more content to the principle of stationary action than equations of motion. Suppose one considers a variation such that
\[
\delta W_{12} = 0,
\]
independently of the choice of initial and final times. We say that the action, which is left unchanged, is invariant under this alteration of path. Then the stationary action principle (1.3) asserts that
\[
\delta W_{12} = G_1 - G_2 = 0,
\]

---

**CHAPTER 1. ACTION PRINCIPLES**

**Notice that there is no equation of motion for v since dv/dt does not occur in the Lagrangian, nor is it multiplied by a time derivative. Consequently, (1.32) refers to a single time and is an equation of constraint.**

**From this third approach, we have the option of returning to either of the other two viewpoints by imposing an appropriate restriction. Thus, if we write (1.28) as**

\[
H(r, p, v, t) = \frac{p^2}{2m} + V(r, t) - \frac{1}{2m}(p - mv)^2,
\]

**and we adopt**

\[
v = \frac{1}{m}p
\]

**as the definition of v, we recover the Hamiltonian description, (1.16) and (1.17). Alternatively, we can present the Lagrangian (1.27) as**

\[
L = \frac{m}{2} \left( \frac{dr}{dt} \right)^2 - V + (p - mv) \cdot \left( \frac{dr}{dt} - v \right) - \frac{m}{2} \left( \frac{dr}{dt} - v \right)^2.
\]

**Then, if we adopt the following as definitions,**

\[
v = \frac{dr}{dt}, \quad p = mv,
\]

**the resultant form of L is that of the Lagrangian viewpoint, (1.4). It might seem that only the definition v = dr/dt, inserted in (1.37), suffices to regain the Lagrangian description. But then the next to last term in (1.37) would give the following additional contribution to δL, associated with the variation δr:**

\[
(p - mv) \cdot \frac{d}{dt} \delta r.
\]

**The advantage of adopting this third approach, which is characterized by the introduction of additional variables, is particularly conspicuous in the action formulation of electrodynamics, where variables, similar to v, appear for which there are no equations of motion.**
or, there is a quantity \( G(t) \) that has the same value for any choice of time \( t \); it is conserved in time. A differential statement of that is
\[
\frac{d}{dt} G(t) = 0. \tag{1.42}
\]
The \( G \) functions, which are usually referred to as generators, express the inter-relation between conservation laws and invariances of the system.

Invariance implies conservation, and vice versa. A more precise statement is the following:

If there is a conservation law, the action is stationary under an infinitesimal transformation in an appropriate variable.

The converse of this statement is also true.

If the action \( W \) is invariant under an infinitesimal transformation (that is, \( \delta W = 0 \)), then there is a corresponding conservation law.

This is the celebrated theorem proved by Amalie Emmy Noether (1882–1935).

Here are some examples. Suppose the Hamiltonian of (1.16) does not depend explicitly on time, or
\[
W_{12} = \int_2^1 \left[ p \cdot dr - H(r, p) dt \right]. \tag{1.43}
\]
Then the variation (which as a rigid displacement in time, amounts to a shift in the time origin)
\[
\delta t = \text{constant} \tag{1.44}
\]
will give \( \delta W_{12} = 0 \) [see the first line of (1.19), with \( \delta r = 0, \delta p = 0, d\delta t/dt = 0, \partial H/\partial t = 0 \)]. The conclusion is that \( G \) in (1.23), which here is just
\[
G_t = -H \delta t, \tag{1.45}
\]
is a conserved quantity, or that
\[
\frac{dH}{dt} = 0. \tag{1.46}
\]
This inference, that the Hamiltonian—the energy—is conserved, if there is no explicit time dependence in \( H \), is already present in (1.22). But now a more general principle is at work.

Next, consider an infinitesimal, rigid rotation, one that maintains the lengths and scalar products of all vectors. Written explicitly for the position vector \( r \), it is
\[
\delta r = \delta \omega \times r, \tag{1.47}
\]
where the constant vector \( \delta \omega \) gives the direction and magnitude of the rotation (see Fig. 1.2). Now specialize (1.17) to
Figure 1.2: $\delta \omega \times \mathbf{r}$ is perpendicular to $\delta \omega$ and $\mathbf{r}$, and represents an infinitesimal rotation of $\mathbf{r}$ about the $\delta \omega$ axis.

$$H = \frac{p^2}{2m} + V(r), \quad (1.48)$$

where $r = |\mathbf{r}|$, a rotationally invariant structure. Then

$$W_{12} = \int_2^1 [\mathbf{p} \cdot \mathbf{d r} - H \, dt] \quad (1.49)$$

is also invariant under the rigid rotation, implying the conservation of

$$G_{\delta \omega} = \mathbf{p} \cdot \delta \mathbf{r} = \delta \omega \cdot \mathbf{r} \times \mathbf{p}. \quad (1.50)$$

This is the conservation of angular momentum,

$$\mathbf{L} = \mathbf{r} \times \mathbf{p}, \quad \frac{d}{dt} \mathbf{L} = 0. \quad (1.51)$$

Of course, this is also contained within the equation of motion,

$$\frac{d}{dt} \mathbf{L} = -\mathbf{r} \times \nabla V = -\mathbf{r} \times \mathbf{r} \frac{\partial V}{\partial r} = 0, \quad (1.52)$$

since $V$ depends only on $|\mathbf{r}|$.

Conservation of linear momentum appears analogously when there is invariance under a rigid translation. For a single particle, (1.21) tells us immediately that $\mathbf{p}$ is conserved if $V$ is a constant, say zero. Then, indeed, the action

$$W_{12} = \int_2^1 \left[ \mathbf{p} \cdot \mathbf{dr} - \frac{p^2}{2m} \, dt \right] \quad (1.53)$$

is invariant under the displacement

$$\delta \mathbf{r} = \delta \epsilon = \text{constant}, \quad (1.54)$$

and

$$G_{\delta \epsilon} = \mathbf{p} \cdot \delta \epsilon \quad (1.55)$$
is conserved. But the general principle acts just as easily for, say, a system of
two particles, \(a\) and \(b\), with Hamiltonian
\[
H = \frac{p_a^2}{2m_a} + \frac{p_b^2}{2m_b} + V(r_a - r_b).
\] (1.56)

This Hamiltonian and the associated action
\[
W_{12} = \int_2^1 [p_a \cdot dr_a + p_b \cdot dr_b - H \, dt]
\] (1.57)
are invariant under the rigid translation
\[
\delta r_a = \delta r_b = \delta \epsilon,
\] (1.58)
with the implication that
\[
G_{\delta \epsilon} = p_a \cdot \delta r_a + p_b \cdot \delta r_b = (p_a + p_b) \cdot \delta \epsilon
\] (1.59)
is conserved. This is the conservation of the total linear momentum,
\[
P = p_a + p_b, \quad \frac{d}{dt} P = 0.
\] (1.60)

Something a bit more general appears when we consider a rigid translation
that grows linearly in time:
\[
\delta r_a = \delta r_b = \delta \mathbf{v} \, t,
\] (1.61)
using the example of two particles. This gives each particle the common addi-
tional velocity \(\delta \mathbf{v}\), and therefore must also change their momenta,
\[
\delta p_a = m_a \delta \mathbf{v}, \quad \delta p_b = m_b \delta \mathbf{v}.
\] (1.62)
The response of the action (1.57) to this variation is
\[
\delta W_{12} = \int_2^1 \left[(p_a + p_b) \cdot \delta \mathbf{v} \, dt + \delta \mathbf{v} \cdot (m_a dr_a + m_b dr_b) - (p_a + p_b) \cdot \delta \mathbf{v} \, dt\right]
= \int_2^1 d[(m_a r_a + m_b r_b) \cdot \delta \mathbf{v}].
\] (1.63)
The action is not invariant; its variation has end-point contributions. But there
is still a conservation law, not of \(G = P \cdot \delta \mathbf{v} t\), but of \(N \cdot \delta \mathbf{v}\), where
\[
N = P t - (m_a r_a + m_b r_b).
\] (1.64)
Written in terms of the center-of-mass position vector
\[
\mathbf{R} = \frac{m_a r_a + m_b r_b}{M}, \quad M = m_a + m_b,
\] (1.65)
the statement of conservation of
\[ N = Pt - MR, \quad (1.66) \]
namely
\[ 0 = \frac{dN}{dt} = P - M \frac{dR}{dt}, \quad (1.67) \]
is the familiar fact that the center of mass of an isolated system moves at the constant velocity given by the ratio of the total momentum to the total mass of that system.

### 1.5 Nonconservation Laws. The Virial Theorem

The action principle also supplies useful nonconservation laws. Consider, for constant \( \delta \lambda \),
\[ \delta r = \delta \lambda r, \quad \delta p = -\delta \lambda p, \quad (1.68) \]
which leaves \( p \cdot dr \) invariant,
\[ \delta(p \cdot dr) = (-\delta \lambda p) \cdot dr + p \cdot (\delta \lambda dr) = 0. \quad (1.69) \]
But the response of the Hamiltonian
\[ H = T(p) + V(r), \quad T(p) = \frac{p^2}{2m}, \quad (1.70) \]
is given by the noninvariant form
\[ \delta H = \delta \lambda (-2T + r \cdot \nabla V). \quad (1.71) \]
Therefore we have, for an arbitrary time interval, for the variation of the action (1.18),
\[ \delta W_{12} = \int_2^1 dt [\delta \lambda (2T - r \cdot \nabla V)] = G_1 - G_2 = \int_2^1 dt \frac{d}{dt} (p \cdot \delta \lambda r) \quad (1.72) \]
or, the theorem
\[ \frac{d}{dt} (r \cdot p) = 2T - r \cdot \nabla V. \quad (1.73) \]
This is an example of the mechanical virial theorem.

For the particular situation of the Coulomb potential between charges, \( V = \text{constant}/r \), where
\[ r \cdot \nabla V = r \frac{d}{dr} V = -V, \quad (1.74) \]
the virial theorem asserts that
\[ \frac{d}{dt} (r \cdot p) = 2T + V. \quad (1.75) \]
1.6. APPENDIX: RELATIVISTIC LAGRANGIAN FOR A SINGLE PARTICLE

We apply this to a *bound* system produced by a force of attraction. On taking the time average of (1.75) the time derivative term disappears. That is because, over an arbitrarily long time interval \( \tau = t_1 - t_2 \), the value of \( r \cdot p(t_1) \) can differ by only a finite amount from \( r \cdot p(t_2) \), and

\[
\frac{d}{dt}(r \cdot p) = \frac{1}{\tau} \int_{t_2}^{t_1} dt \frac{d}{dt} r \cdot p = \frac{r \cdot p(t_1) - r \cdot p(t_2)}{\tau} \to 0,
\]

as \( \tau \to \infty \). The conclusion,

\[
2T = -\tilde{V},
\]

is familiar for circular motion.

Here is one more example of a nonconservation law: Consider the variations

\[
\delta r = \delta \lambda \frac{r}{r}, \quad \delta p = -\delta \lambda \left( \frac{p}{r} - \frac{r p \cdot r}{r^3} \right) = \delta \lambda \frac{r \times (r \times p)}{r^3}.
\]

Again \( p \cdot dr \) is invariant:

\[
\delta(p \cdot dr) = \delta \lambda \left( \frac{p}{r} - \frac{r p \cdot r}{r^3} \right) \cdot dr + p \cdot \left( \delta \lambda \frac{dr}{r} - \delta \lambda \frac{r \cdot dr}{r^3} \right) = 0,
\]

and the change of the Hamiltonian (1.70) is now

\[
\delta H = \delta \lambda \left[ -\frac{L^2}{mr^3} + \frac{r}{r} \cdot \nabla V \right].
\]

The resulting theorem, for \( V = V(r) \), is

\[
\frac{d}{dt} \left( \frac{r}{r} \cdot p \right) = \frac{L^2}{mr^3} - \frac{dV}{dr},
\]

which, when applied to the Coulomb potential, gives the bound-state time average relation

\[
\frac{L^2}{m} \left( \frac{1}{r^3} \right) = -\left( \frac{V}{r} \right).
\]

This relation is significant in hydrogen fine-structure calculations.

### 1.6 Appendix: Relativistic Lagrangian for a single particle

Consider a single particle of rest mass \( m_0 \) moving in a potential \( V(r,t) \). The Lagrangian is

\[
L = -m_0c^2 \sqrt{1 - \frac{r^2}{c^2}} - V(r,t).
\]
CHAPTER 1. ACTION PRINCIPLES

Note when $|\mathbf{v}| = |\dot{\mathbf{r}}| \ll 1$, the first term in the Lagrangian is $-m_0c^2 + \frac{1}{2}m_0v^2$, which, up to an irrelevant constant, gives the Lagrangian (1.4). Under a variation of the path, $\mathbf{r} \rightarrow \mathbf{r} + \delta\mathbf{r}$, and a variation of the time coordinate, $t \rightarrow t + \delta t$, the action changes by

$$\delta W_{12} = \int_{t_1}^{t_2} dt \left[ \dot{\mathbf{r}} \cdot \frac{\partial L}{\partial \mathbf{r}} + \frac{d}{dt} \dot{\mathbf{r}} \cdot \frac{\partial L}{\partial \dot{\mathbf{r}}} + \delta t \frac{\partial L}{\partial t} + \frac{d\delta t}{dt} \frac{\partial L}{\partial \dot{\mathbf{r}}} \cdot \dot{\mathbf{r}} \right],$$

(1.84)

since under a time variation,

$$\delta \dot{t} = \dot{\mathbf{r}} \left( -\frac{d\delta t}{dt} \right).$$

(1.85)

Here the momentum is

$$p = \frac{\partial L}{\partial \dot{\mathbf{r}}} = \frac{m_0 \dot{\mathbf{r}}}{\sqrt{1 - (\dot{\mathbf{r}})^2/c^2}}.$$  

(1.86)

Upon integration by parts, we obtain

$$\delta W_{12} = \int_{t_1}^{t_2} dt \left\{ \frac{d}{dt} [\delta \mathbf{r} \cdot \mathbf{p} - \delta t E] + \delta \mathbf{r} \cdot \left[ \frac{d}{dt} \mathbf{p} + \frac{\partial L}{\partial \mathbf{r}} \right] + \delta t \left[ \frac{dE}{dt} - \frac{\partial V}{\partial t} \right] \right\}. $$

(1.87)

Here the relativistic energy appears,

$$E = \mathbf{p} \cdot \dot{\mathbf{r}} - L = \frac{m_0c^2}{\sqrt{1 - (\dot{\mathbf{r}})^2/c^2}} + V,$$

(1.88)

where we see the appearance of the relativistic mass energy, $E = mc^2$,

$$m = \frac{m_0}{\sqrt{1 - v^2/c^2}}.$$  

(1.89)

From the variational principle, we see that the generators are

$$G = \mathbf{p} \cdot \delta \mathbf{r} - E\delta t,$$

(1.90)

and the equation of motion is, in terms of the relativistic momentum (1.86),

$$\frac{d}{dt} \mathbf{p} = -\frac{\partial}{\partial \mathbf{r}} V,$$

(1.91)

while the energy is not conserved if the potential depends explicitly upon time:

$$\frac{d}{dt} E = \frac{\partial}{\partial t} V.$$  

(1.92)

1.7 Problems for Chapter 1

1. Suppose the system consists of $N$ particles interacting through a pairwise potential $V(\mathbf{r}_a - \mathbf{r}_b)$. Write down the Lagrangian and obtain the equations of motion. What is the Hamiltonian, $H(\mathbf{r}_a, \mathbf{p}_a)$? Show that energy and total momentum are conserved. What is required for angular momentum to be conserved?
2. For a free relativistic particle of rest mass $m_0$, the energy is

$$E = \sqrt{p^2c^2 + m_0^2c^4}.$$

Use this as the Hamiltonian $H$, and from the Lagrangian

$$L = p \cdot \frac{dr}{dt} - H$$

determine the relationship between the velocity $v = \frac{dr}{dt}$ and the momentum. Compute the energy in terms of the velocity. Write the Lagrangian in terms of $v$.

3. Consider a particle bound by a potential of the form

$$V = ar^b.$$ 

Derive the time-averaged virial theorem relating $T$ to $V$. What is the smallest value of $b$ for which a bound state can occur?
